

5 APPENDIX 5.1 – LVIA METHODOLOGY

5.1 Introduction

- 5.1.1 This methodology has been prepared by chartered landscape architects at Optimised Environments Ltd (OPEN) and describes in detail the methodology that has been used to carry out the Landscape and Visual Impact Assessment (LVIA). This Technical Appendix has been prepared to accompany Chapter 5: LVIA in Volume 1 of the Pen March Wind Farm (hereafter the Proposed Scheme) EIA Report.
- 5.1.2 The LVIA identifies and assesses the significance of changes resulting from the Proposed Scheme on both the landscape as an environmental resource and on people's views and visual amenity.

Guidance

- 5.1.3 The following sources have been used in the formulation of methodology for the assessment and the presentation of visual representations:
- Landscape Institute with the Institute of Environmental Management and Assessment (2013). Guidelines for Landscape and Visual Impact Assessment, Third Edition (GLVIA3);
 - Carys Swanwick Department of Landscape University of Sheffield and Land Use Consultants for The Countryside Agency and NatureScot (2002). Landscape Character Assessment Guidance for England and Scotland;
 - NatureScot (2021) Assessing the Cumulative Impact of Onshore Wind Energy Developments;
 - NatureScot (2020) Assessing impacts on Wild Land Areas - Technical Guidance;
 - NatureScot (2017) Siting and Designing Wind Farms in the Landscape Version 3a;
 - NatureScot (2017) Visual Representation of Wind Farms, Version 2.2;
 - NatureScot (DRAFT 2018-2019 or as updated) Guidance for Assessing the Effects on Special Landscape Qualities;
 - Landscape Institute (2019) Technical Guidance Note 2/19 Residential Visual Amenity Assessment; and
 - Landscape Institute (2019) Visual representation of Development Proposals: Landscape Institute Technical Guidance Note 06/19.

GLVIA3

- 5.1.4 OPEN's LVIA methodology generally follows the guidance set out in the GLVIA3. Where it diverges from specific aspects of the guidance, in a small number of areas, reasoned professional justification for this is provided as follows.
- 5.1.5 GLVIA3 sets out an approach to the assessment of magnitude of change in which three separate considerations are combined within the magnitude of change rating. These are the size or scale of the effect, its geographical extent and its duration and reversibility. This approach is to be applied in respect of both landscape and visual receptors. OPEN considers that the process of combining all three considerations in one rating can distort the aim of identifying significant effects of windfarm development. For example, an

increased magnitude of change, based on size or scale, may be reduced to a lower rating if it occurred in a localised area and for a short duration. This might mean that a potentially significant effect would be overlooked if effects are diluted down due to their geographical extents and/or duration or reversibility.

- 5.1.6 OPEN has chosen to keep the consideration of the size or scale of the effect, its geographical extent and its duration and reversibility separate, by basing the magnitude of change on size or scale to determine where significant and not significant effects occur, and then describing the geographical extents of these effects and their duration and reversibility separately. Duration and reversibility are stated separately in relation to the assessed effects (i.e. as short/medium/long-term and temporary/permanent) and are considered as part of drawing conclusions about significance, combining with other judgements on sensitivity and magnitude, to allow a final judgement to be made on whether each effect is significant or not significant.

Information and Data Sources

- 5.1.7 The assessment is initiated through a desk study of the Proposed Scheme and the LVIA Study Area. This desk study identifies aspects of the landscape and visual resource that are considered in the LVIA, including landscape related planning designations, landscape character typology, operational and potential cumulative windfarms, and views from routes and settlements.
- 5.1.8 The desk study utilises Geographic Information System (GIS) and ReSoft WindFarm software to explore the potential visibility of the Proposed Scheme. The resultant Zone of Theoretically (ZTV) diagrams and wirelines provide an indication of which landscape and visual receptors are likely to be key in the assessment.
- 5.1.9 Landscape characterisation information and data has been obtained from the following sources: NRW, 2013 - National Landscape Character Areas; LANDMAP the Welsh landscape baseline (<https://naturalresources.wales/guidance-and-advice/business-sectors/planning-and-development/evidence-to-inform-development-planning/landmap-the-welsh-landscape-baseline/?lang=en>); Bannau Brycheiniog Landscape Character Assessment, 2012 (Fiona Fyfe Associates); Landscape Character Assessment for Bridgend County Borough, 2013 (LUC); Caerphilly County Borough Smaller Scale Wind Turbine Development, 2015 (Gillespies and Caerphilly County Borough Council); Heads of the Valleys Smaller Scale Wind Turbine Development, Landscape Sensitivity and Capacity Study Final Report, 2015 (Gillespies); Monmouthshire County Council. Draft Supplementary Planning Guidance, 'Landscape', 2019. (Chris Blandford Associates and TACP); Neath Port Talbot LANDMAP Landscape Assessment Final Report, 2004 (White Consultants); and Sensitivity and Capacity Study for Renewable Energy Development Blaenau Gwent CBC and Torfaen CBC, 2021, TACP.

Study Area

- 5.1.10 The initial step in the LVIA is the establishment of the Study Area for the assessment. Guidance developed by NatureScot (Visual Representation of Windfarms Version 2.2, February 2017) indicates that an area with a radius of 45 km from the nearest turbine is appropriate for the turbines of the size proposed in the Proposed Scheme. The 45km study area was also agreed with consultees through scoping. The 45 km radius is shown on Figure 5.1.

- 5.1.11 A more detailed 15km study area for was proposed at scoping stage in which to assess the landscape character effects. NRW commented that according to LANDMAP guidance note 3 that significant landscape character effects may occur beyond 20km. Guidance note 3 has been replaced with guidance note 46 which provides more defined guidance on study areas relating to development types and scales. In following that guidance a study area of 26km has been used in the LVIA for the assessment of landscape character effects.
- 5.1.12 Visual receptors have been considered within a 45km study area, with a more detailed focus for those receptors found closer to the site, including for – settlements within 10km, Public Rights of Way within 5km and individual properties within 2km (as considered in the RVAA and in accordance with LI guidance). See appendix 5.4 for further description of the RVAA study area.

Desk Study

- 5.1.13 The assessment is initiated through a desk study of the Site and Study Area as described above. ZTV analysis of the Proposed Scheme has been carried out for the Study Areas outlined above (including cumulative ZTVs, CZTVs), as has mapping of landscape character, landscape related designations, wild land areas and principal visual receptors. The Study Areas are not intended to provide a boundary beyond which the Proposed Scheme would not be seen, but rather to define the areas within which it may have a significant landscape or visual effect. A significant effect is, in reality, very unlikely to occur towards the edges of the identified Study Areas.
- 5.1.14 The desk study also utilises Geographic Information System (GIS) and Resoft Windfarm software to explore the potential visibility of the Proposed Scheme. The resultant ZTV diagrams and wirelines provide an indication of which landscape and visual receptors are likely to be key in the assessment.

Field Survey

- 5.1.15 To inform the LVIA and layout design process, field survey was undertaken between November 2020 and October 2021. Viewpoint photography was captured during field survey visits in periods of good visibility. Field surveys were carried out throughout the 45 km radius area, although surveys were concentrated within the areas shown on the ZTV to gain theoretical visibility of the Proposed Scheme.
- 5.1.16 Field survey included visits to viewpoints as well as extensive travel around the Study Area to consider potential effects (including cumulative) on landscape character and on the experience of views seen from travel routes through the landscape. These visits have allowed the landscape character and the visual amenity of the Study Area to be experienced in a range of different conditions and seasonal variation. The field survey allows the assessors to judge the likely scale, distance, extent and prominence of the Proposed Scheme directly.
- 5.1.17 The landscape of the Site was assessed for any particular features that contribute to the landscape character of the Site or are important to the wider landscape setting. In particular, the form and pattern of the land was assessed from the Site and surrounding area to better understand its character and to take these qualities into account in the siting and design of the Proposed Scheme. The landscape character types for the Study Area were reviewed and the key characteristics of the landscape were identified. The

field surveys provided an experience of the character types of the Study Area and verification of how these areas might be affected by the Proposed Scheme. Visual amenity was surveyed including both static and sequential views, from receptors representative of the range of views and viewer types likely to experience the Proposed Scheme. Views from a variety of distances, aspects, elevations and extents were included. Receptor types include individual properties and settlements; main transport routes; main visitor locations; areas of cultural significance; the range of landscape character types within the Study Area; and the cumulative effects of the Proposed Scheme in combination with other existing or proposed windfarms in the Study Area.

5.2 Types of Landscape and Visual Effects

- 5.2.1 The LVIA is intended to determine the effects that the Proposed Scheme would have on the landscape and visual resource.
- 5.2.2 For the purpose of assessment, the potential effects on the landscape and visual resource are grouped into three categories: landscape effects, visual effects and cumulative landscape and visual effects, each of which is briefly described as follows.

Landscape Effects

- 5.2.3 The LVIA considers the effects of the Proposed Scheme on the landscape as a resource. Landscape effects are either direct effects on the physical fabric of the site, or effects on landscape character. The assessment of landscape effects is carried out as follows:
- 5.2.4 Assessment of physical effects: physical effects are direct effects on the physical fabric of the site, such as the removal of trees and alteration to ground cover. This category of effects is made up of landscape elements, which are the components of the landscape such as hedgerows or woodland that may be physically affected by the Proposed Scheme.
- 5.2.5 Assessment of effects on landscape character: landscape character is the distinct and recognisable pattern of elements that occurs consistently in a particular type of landscape, and the way that this pattern is perceived. Effects on landscape character arise either through the introduction of new elements that alter this pattern of elements, or through visibility of the Proposed Scheme, which may alter the way in which the pattern of elements is perceived. This category of effects is considered in terms of landscape character receptors, which fall into two groups; landscape character types/areas and landscape designations.

Visual Effects

- 5.2.6 The LVIA considers the effect of the Proposed Scheme on views and visual amenity. Visual effects include effects on visual receptors, i.e. groups of people that may experience an effect, and views (viewpoints). The visual assessment is carried out as follows:
- 5.2.7 An assessment of the effects of the Proposed Scheme on views from principal visual receptors, including residents of settlements, motorists using roads, people using recreational routes, features and attractions throughout the Study Area (as ascertained through the baseline study); and

- 5.2.8 An assessment of the effects of the Proposed Scheme on representative viewpoints that have been selected to assess the effect on locations relevant to these visual receptors and from specific viewpoints, chosen because they are key or promoted viewpoints in the landscape.

Cumulative Effects

- 5.2.9 Cumulative landscape and visual effects arise where the study areas for two or more wind farms overlap so that both are experienced at proximity where they may have a greater incremental effect, or where wind energy developments may combine to have a sequential effect, irrespective of any overlap in study areas. This means that the addition of the Proposed Scheme to a situation where other wind farms are apparent in the baseline or a potential future baseline landscape and visual context may result in a greater effect than where the Proposed Scheme is seen in isolation. The main assessment of the effects of the Proposed Scheme takes into account its addition to a baseline landscape that contains the operational/under construction wind farms.

Significance of effects

- 5.2.10 The objective in assessing the effects of the Proposed Scheme is to predict the significant effects of the Proposed Scheme on the landscape and visual resource. In accordance with the Electricity Works (Environmental Impact Assessment) (Scotland) Regulations 2017 (the EIA Regulations) the LVIA effects are assessed to be either significant or not significant.
- 5.2.11 The significance of effects is assessed through a combination of the sensitivity of the landscape receptor or view and the magnitude of change that would result from the addition of the Proposed Scheme. While this methodology is not reliant on the use of a matrix to determine the conclusion of a significant or not significant effect, a matrix is included in Table 5.1 below to illustrate how combinations of sensitivity and magnitude of change ratings can give rise to significant effects. On this basis potential impacts are assessed as of Negligible, Minor, Moderate-Minor, Moderate, Moderate-Major and Major. In those instances where the magnitude has been assessed as 'no change' and the level of effect is recorded as 'no effect'.
- 5.2.12 For the purposes of this assessment, any effects with a significance level of Major and Moderate-Major have been deemed significant in EIA terms (dark grey shaded boxes in Table 5.1). 'Moderate' levels of effect have the potential, subject to the assessor's professional judgement, to be considered as significant or not significant, depending on the sensitivity and magnitude of change factors evaluated (light grey shaded boxes in Table 5.1). These assessments are explained as part of the assessment, where they occur. Significance can therefore occur at a range of levels depending on the magnitude and sensitivity, however in all cases, a significant effect is considered more likely to occur where a combination of the variables results in the Proposed Scheme having a defining effect on the landscape character or view. Definitions are not provided for the individual categories of significance shown in the matrix and the reader should refer to the detailed definitions provided for the factors that combine to inform sensitivity and magnitude
- 5.2.13 Effects assessed as being either Moderate-Minor, Minor or Negligible level are assessed as not significant (white boxes in Table 5.1.1).

- 5.2.14 In line with the emphasis placed in GLVIA3 upon the application of professional judgement, an overly mechanistic reliance upon a matrix is avoided through the provision of clear and accessible narrative explanations of the rationale underlying the assessment made for each landscape and visual receptor.

Table 5.1.1: Matrix used to guide determination of effect significance.

Magnitude Sensitivity	High	Medium-High	Medium	Medium-Low	Low	Negligible
High	Major (Significant)	Major (Significant)	Moderate-Major (Significant)	Moderate (Significant / Not Significant)	Moderate - Minor (Not significant)	Minor (Not significant)
Medium-High	Major (Significant)	Moderate-Major (Significant)	Moderate (Significant / Not Significant)	Moderate (Significant / Not Significant)	Moderate - Minor (Not significant)	Minor (Not significant)
Medium	Moderate-Major (Significant)	Moderate (Significant / Not Significant)	Moderate (Significant / Not Significant)	Moderate - Minor (Not significant)	Minor (Not significant)	Minor (Not significant)
Medium-Low	Moderate (Significant / Not Significant)	Moderate (Significant / Not Significant)	Moderate - Minor (Not significant)	Minor (Not significant)	Minor (Not significant)	Negligible (Not significant)
Low	Moderate (Significant / Not Significant)	Moderate - Minor (Not significant)	Minor (Not significant)	Minor (Not significant)	Negligible (Not significant)	Negligible (Not significant)

- 5.2.15 Significant effects occur where the Proposed Scheme would provide a defining influence on a landscape element, landscape character receptor or view; or where changes of a lower magnitude occur on a landscape element, landscape character receptor or view that is of particularly high sensitivity. A not significant effect occurs where the effect of the Proposed Scheme is not material, whereby the baseline characteristics of the landscape element, landscape character receptor or view continue to provide the definitive influence, or where the small scale of change experienced by a high sensitivity receptor is such as to be considered not significant.
- 5.2.16 Significant cumulative effects occur where the addition of the Proposed Scheme to the baseline under consideration (which may include other wind energy developments), leads to windfarms becoming a prevailing landscape and visual characteristic or where

the Proposed Scheme adversely contrasts with the scale or design of an existing or proposed development.

5.3 Assessment of Landscape Effects

- 5.3.1 Landscape character is the distinct and recognisable pattern of elements that occurs consistently in a particular type of landscape, and the way that this pattern is perceived. Effects on landscape character arise either through the introduction of new elements that physically alter this pattern of elements, or through visibility of the Proposed Scheme, which may alter the way in which the pattern of elements is perceived. This category of effects is made up of physical effects and effects on landscape character (landscape character types and designated areas).

5.4 Assessment of Physical Landscape Effects

- 5.4.1 The physical effects of the Proposed Scheme are restricted to the area of the site where existing landscape elements may be changed. Physical effects are the direct effects as a result of the Proposed Scheme on the fabric of the site, such as the removal of trees and alteration to ground cover. The objective of the assessment of physical effects is to determine what the likely physical effects of the Proposed Scheme would be, which landscape elements would be affected, and whether these effects would be significant or not significant. The variables considered in the sensitivity of landscape elements and the magnitude of change that the Proposed Scheme would have on them are described as follows.

Sensitivity of Landscape Elements

- 5.4.2 The sensitivity of a landscape element is an expression of its value and quality, and susceptibility to change.
- The value of a landscape element is a reflection of its importance in the pattern of elements which constitute the landscape character of the area. For example, the value of woodland is likely to be increased if it provides an important component of the local landscape character. If a landscape element is particularly rare, as a remnant of an historic landscape layout for example, its value is likely to be increased; and
 - The susceptibility of a landscape element to change is a reflection of the degree to which landscape elements are vulnerable to the change proposed or are able to resist/accommodate the change proposed.
- 5.4.3 The evaluation of sensitivity is described for each receptor in the assessment. Levels of sensitivity: high, medium-high, medium, medium-low and low, are applied.

Magnitude of Change on Landscape Elements

- 5.4.4 The magnitude of change on landscape elements is quantifiable and is expressed in terms of the degree to which a landscape element would be removed or altered by the Proposed Scheme, the extent of existing landscape elements that would be lost and the contribution of that element to the character of the landscape. Definitions of magnitude of change are applied in order that the process of assessment is made clear. These are:

- High: where the Proposed Scheme would result in the complete removal or substantial alteration of a landscape element;
- Medium: where the Proposed Scheme would result in the removal of a notable part of a landscape element or a notable alteration to a landscape element;
- Low: where the Proposed Scheme would result in the removal of a minor part of a landscape element or a minor alteration to a landscape element;
- Negligible: where the Proposed Scheme would result in the removal of a negligible amount of a landscape element or is barely discernible; and
- None: where the Proposed Scheme would result in no change to the landscape element.

5.4.5 There may also be intermediate levels of magnitude of change, such as medium-high or medium-low, where the change falls between definitions.

Significance of Effects on Landscape Elements

5.4.6 The significance of the effect on landscape elements is dependent on all of the factors considered in the sensitivity of the receptor and the magnitude of change upon it, and by applying professional judgement to assess whether or not the Proposed Scheme would have an effect that is significant or not significant.

5.4.7 A significant effect would occur where the degree of removal or alteration of the landscape element is such that the landscape element would be redefined (although the landscape character may not necessarily be redefined). If the landscape element is of a high sensitivity, a significant effect can occur with a limited degree of removal or alteration. A not significant effect would occur where the form of the landscape element is not redefined as a result of the Proposed Scheme. If the landscape element is of lower sensitivity, it may undergo a higher level of removal or alteration yet remain as a not significant effect.

5.5 Assessment of Effects on Landscape Character

5.5.1 The objective of the assessment of effects on landscape character is to determine what the likely effects of the Proposed Scheme would be, which landscape character receptors would be affected, and whether these effects would be significant or not significant. The methodology for the assessment of effects on landscape character involves the undertaking of a baseline study, evaluation of sensitivity, magnitude of change and an assessment of significance.

Landscape Baseline and Scope Assessment

5.5.2 The landscape baseline provides an understanding of the landscape in the area that may be affected - its constituent elements, its character, distinctiveness, condition and value, and the way this varies spatially. The landscape baseline describes aspects of the landscape that may be significantly affected, as defined in Schedule 4 of the EIA Regulations. Establishing the landscape baseline will, when reviewed alongside the description of the Proposed Scheme, form the basis for the identification and description of the landscape effects of the Proposed Scheme. The baseline description of the landscape that may be affected is primarily determined by the physical footprint of the Proposed Scheme components and their ZTV.

- 5.5.3 An overview of the landscape baseline is described, and a scope assessment identifies landscape receptors that may experience significant effects, which require to be assessed in full. A detailed description of the baseline is provided for each landscape receptor that may experience significant effects, allowing the full baseline to be described for landscape receptors that may be significantly affected. Those receptors which are identified as not having the potential to undergo significant effects and significant cumulative effects are not included in the subsequent detailed assessment, but are noted with reasons given for their exclusion.
- 5.5.4 The baseline study of each landscape character receptor collates and presents information relevant to the assessment drawn from a combination of desk study and fieldwork. The baseline study covers the following issues:
- the description of the landscape character receptor drawn from the relevant documentation such as the Landscape Character Assessment or citations in respect of landscape designations;
 - a description of the landscape character receptor based on field work to determine how typical or not the landscape character receptor is in relation to documented descriptions;
 - those features and patterns of the landform, land-cover and land use which make the landscape character receptor distinctive;
 - the visual and sensory experience of the landscape and how it associates with other landscapes including, in particular, the landscape character receptor where the Proposed Scheme is located; and
 - how change in this landscape character receptor, either through natural or human processes, is presently affecting character and how they are predicted to affect character in the future. This may include operational windfarms where they are a feature of the baseline landscape context.
- 5.5.5 The landscape baseline also describes current pressures that may cause change in the landscape in the future, in particular drawing on information for wind energy developments that are not yet present in the landscape but are at other stages in the Proposed Scheme and consenting process. Operational and under construction wind energy developments are regarded as part of the baseline landscape character of the area. Any changes resulting from the Proposed Scheme are assessed within this context in the assessment of landscape and visual effects.

Sensitivity of Landscape Character Receptors

- 5.5.6 The sensitivity of a landscape character receptor is an expression of the combination of the judgements made about the susceptibility of the receptor to the specific type of change or the development proposed, and the value related to that receptor.

Value of the Landscape Receptor

- 5.5.7 The value of a landscape character receptor is classified as high, medium-high, medium, medium-low or low and the basis for this assessment is made clear using evidence and professional judgement, based on the following range of factors:
- Landscape designations: A receptor that lies within the boundary of a recognised landscape related planning designation will be of increased value, depending on the proportion of the receptor that is covered and the level of importance of the designation; international, national, regional or local. It is important to note that the

absence of designations does not preclude local resource value, as an undesignated landscape character receptor may be important as a resource in the local or immediate environment, particularly when experienced in comparison with other nearby landscapes.

- **Landscape quality:** The quality of a landscape character receptor is a reflection of its attributes, such as scenic quality, sense of place, rarity and representativeness and the extent to which these attributes have remained intact. A landscape with consistent, intact and well-defined, distinctive attributes is generally considered to be of higher quality and, in turn, higher value, than a landscape where the introduction of inappropriate elements has detracted from its inherent attributes.
- **Landscape experience:** The experience of the landscape character receptor can add to its value and relates to a number of factors including the perceptual responses it evokes, the cultural associations that may exist in literature or history, or the iconic status of the landscape in its own right, the recreational value of the landscape for outdoor pursuits, and the contribution of other values relating to the nature conservation or archaeology of the area.

Susceptibility to Change

5.5.8 The susceptibility of a landscape character receptor to change is a reflection of its ability to accommodate the changes that would occur as a result of the addition of the Proposed Scheme. The assessment of the susceptibility of the landscape receptor to change is classified as high, medium-high, medium, medium-low or low and the basis for this assessment is made clear using evidence and professional judgement, based on the following criteria:

- **The specific nature of the Proposed Scheme:** The susceptibility of landscape receptors is assessed in relation to change arising from the specific development proposed, including the specific components and features of the Proposed Scheme proposed, its size, scale, location, context and characteristics.
- **Landscape character:** The key characteristics of the existing landscape character of the receptor is considered in the evaluation of susceptibility as they determine the degree to which the receptor may accommodate the influence of the Proposed Scheme. For example, a landscape that is of a particularly wild and remote character may have a higher susceptibility to the influence of the Proposed Scheme due to the contrast that it would have with the landscape, whereas a developed, industrial landscape, where built elements and structures are already part of the landscape character, may have a lower susceptibility. However, there are instances when the quality of a landscape may have been degraded to an extent whereby it is considered to be in a fragile state and therefore a degraded landscape may have a higher susceptibility to the Proposed Scheme.
- **Landscape association:** The extent to which the Proposed Scheme would influence the character of the landscape receptors across the Study Area, relates to the associations that exist between the landscape receptor where the Proposed Scheme is located and the landscape receptor from which the Proposed Scheme is being experienced. In some situations this association would be strong where the landscapes are directly related, for example the influence on a valley landscape by an enclosing upland landscape where the Proposed Scheme is set along the skyline, and in other situations weak where the landscape association is less important; for example, where the Proposed Scheme lies inland of a coastal landscape that has its main focus outwards over the sea.

Sensitivity Rating

- 5.5.9 An overall sensitivity assessment of the landscape receptor is made by combining the assessment of the value of the landscape character receptor and its susceptibility to change. An overall level of sensitivity is applied for each landscape receptor: high, medium-high, medium, medium-low and low; by combining individual assessments of the value of the receptor and its susceptibility to change. The basis for the assessments is made clear using evidence and professional judgement in the evaluation of sensitivity for each receptor. Criteria that tend towards higher or lower sensitivity are set out in Table 5.1.2.

Table 5.1.2: Sensitivity to Change – Landscape Receptors

Criteria tending towards higher or lower sensitivity		
	High →	Medium → Low
Value	Designated landscapes with national policy level protection or defined for their natural beauty. Higher quality landscapes with consistent, intact and well-defined, distinctive attributes. Rare or unique landscape character types or features. Aesthetic or perceptual aspects of designated wildlife, ecological or cultural heritage features that contribute to landscape character. Evidence that the landscape is valued or used substantially for recreational activity. Landscape with perceptual qualities of wildness, remoteness or tranquillity. Landscape with strong cultural associations that contribute to perceptions of scenic quality.	Landscapes without formal designation. Despoiled or degraded landscape with little or no evidence of being valued by the community. Lower quality landscapes with indistinct elements or features that detract from its inherent attributes. Widespread or 'common' landscape character types or features. Limited or no wildlife, ecological or cultural heritage features, or limited contribution to landscape character. No evidence that the landscape is used for recreational activity. Landscape with inherent character has been changed by human activity. Landscape with few cultural associations.
	High →	Medium → Low
Susceptibility to Change	Landscape which is likely or liable to be influenced by the Proposed Scheme. Landscape vulnerable or fragile to change through the loss or addition of features that would alter key landscape characteristics. Landscape which lacks the ability to resist/accommodate the change that is likely to occur as a result of the Proposed Scheme. Landscape of high quality/in good condition. Aesthetic or perceptual aspects of landscape are susceptible to changes associated with features of Proposed Scheme.	Landscape which is unlikely or not liable to be influenced by the Proposed Scheme. Robust landscape, able to accommodate change or loss of features without altering key characteristics. Landscape which has the ability to resist/accommodate the change that is likely to occur as a result of the Proposed Scheme. Landscape of low quality/in poor condition. Aesthetic or perceptual aspects of landscape may accommodate changes associated with features of Proposed Scheme. Weak and indirect association between Proposed Scheme and the landscape receptor.

	Strong or direct association between Proposed Scheme and the landscape receptor. Landscape which is directly exposed to the Proposed Scheme and has highest degree of exposure.	Landscape which is not directly exposed to the Proposed Scheme and has degree of concealment/screening.
Sensitivity to Change	High 	Medium  Low

Magnitude of Change on Landscape Character Receptors

- 5.5.10 The magnitude of change on views is an expression of the scale of the change that would result from the Proposed Scheme and is dependent on a number of variables regarding the size or scale of the change. An assessment is also made of the geographical extent of the area over which this would occur and the duration and reversibility of such changes. The basis for this assessment is made clear using evidence and professional judgement, based on the following criteria.

Size or Scale of Change

- 5.5.11 This criterion relates to the size or scale of change to the landscape that would arise as a result of the Proposed Scheme, based on the following factors:
- The degree to which the pattern of elements that makes up the landscape character would be altered by the Proposed Scheme, through removal or addition of elements in the landscape, in this instance. The magnitude of change would generally be higher if key features that make up the landscape character are extensively removed or altered, and if many new components are added to the landscape;
 - The extent to which the Proposed Scheme would change, physically or perceptually, the characteristics that may be important in the creation of the distinctive character of the landscape. This may include the scale of the landform, its relative simplicity or irregularity, the nature of the landscape context, the grain or orientation of the landscape, the degree to which the receptor is influenced by external features and the juxtaposition of the Proposed Scheme with these key characteristics;
 - The degree to which landscape character receptors would be changed by the addition of the Proposed Scheme in place of or in addition to baseline wind energy developments that are already present in the landscape. If the Proposed Scheme is located in a landscape receptor that is already affected by wind energy development, this may reduce the magnitude of change, particularly if there is a high level of integration and the developments form a unified and cohesive feature in the landscape. The converse could also be applicable;
 - The landscape context in which the Proposed Scheme and other wind energy development are located. If the Proposed Scheme is located in a similar landscape context, the magnitude of change is likely to be lower as they relate consistently to key landscape characteristics. If developments are located in different landscape settings, this can lead to a perception that wind energy development is unplanned and uncoordinated, affecting a wide range of landscape characters and blurring the distinction between them;
 - The scale of the landscape, landform and patterns of the landscape. A large-scale landscape can provide a more appropriate receiving environment than a more

intimate, small-scale setting where development may result in uncomfortable scale comparisons and increase the magnitude of change;

- The distance between the landscape character receptor and the Proposed Scheme. Generally, the greater the distance, the lower the scale of change as the Proposed Scheme would constitute a less apparent influence on the landscape character; and
- The extent of the Proposed Scheme that would be seen from the landscape receptor. Visibility of the Proposed Scheme may range from one turbine blade tip to all of the turbines, and generally the greater the extent of the Proposed Scheme that can be seen, the greater the change.

Geographical Extent

- 5.5.12 The geographical extent over which the landscape effects would be experienced is also assessed, which is distinct from the size or scale of effect. This evaluation is not combined in the assessment of the level of magnitude, but instead expresses the extent of the receptor that would experience a particular magnitude of change and can therefore affect the geographical extents of the significant and non-significant effects.
- 5.5.13 The extent of the effects would vary depending on the specific nature of the Proposed Scheme and is principally assessed through analysis of the extent of visibility of physical change to the landscape or the extent to which the landscape character would change through visibility of the Proposed Scheme.

Duration and Reversibility

- 5.5.14 The duration and reversibility of landscape effects are based on the period over which the Proposed Scheme is likely to exist and the extent to which the Proposed Scheme would be removed, and its effects reversed at the end of that period. Duration and reversibility are not incorporated into the overall magnitude of change and are stated separately in relation to the assessed effects.

Magnitude of Change Rating

- 5.5.15 An overall assessment of the magnitude of change resulting from the Proposed Scheme on the landscape receptor is made by combining the assessments of size or scale of change and geographical extent. The basis for the assessment of magnitude for each receptor is made clear using evidence and professional judgement. The levels of magnitude of change that can occur are defined as follows:
- High: the Proposed Scheme would result in a major alteration to the baseline characteristics of the landscape, providing the prevailing influence and/or introducing elements that are uncharacteristic in the receiving landscape;
 - Medium: the Proposed Scheme would result in a moderate alteration to the baseline characteristics of the landscape, providing a readily apparent influence and/or introducing elements potentially uncharacteristic in the receiving landscape;
 - Low: the Proposed Scheme would result in a minor alteration to the baseline characteristics of the landscape, providing a slightly apparent influence and/or introducing elements that are characteristic in the receiving landscape;
 - Negligible: the Proposed Scheme would result in a negligible alteration to the baseline characteristics of the landscape, providing a barely discernible influence and/or introducing elements that are substantially characteristic in the receiving landscape; and

- None: the Proposed Scheme would result in no change to the baseline characteristics of the landscape.

5.5.16 There may also be intermediate levels of magnitude of change, such as medium-high and medium-low, where the change falls between definitions. Criteria that tend towards higher or lower magnitude of change are set out in Table 5.1.3.

Table 5.1.3: Magnitude to Change Criteria – Landscape Receptors

Criteria tending towards higher or lower magnitude			
	High → Medium → Low → Negligible		
Size or scale of change	Major loss of existing landscape elements which contribute to the landscape character. Major alteration to pattern of elements, or perception of landscape pattern, through removal or addition of landscape elements. Major change to key characteristics which define the distinctive character of the landscape. Proposed Scheme located within or close to landscape receptor and results in large scale change to its landscape character. Large amount of Proposed Scheme visible resulting in higher scale of change. Proposed Scheme contrasts with other existing windfarms in pattern, scale and relationship to key characteristics, creating a confusing or inconsistent image or relationship to key characteristics.	Minor or negligible loss of existing landscape elements. Minor alteration to pattern of elements, or perception of landscape pattern. Minor change to key characteristics, or changes to characteristics which are not part of inherent distinctiveness. Proposed Scheme located at long distance outside landscape receptor and result in small scale change to its landscape character. Small amount of Proposed Scheme visible resulting in lower scale of change. Proposed Scheme consolidates existing windfarms, relates consistently to a key characteristic of the landscape and/or has a high level of integration forming a unified and cohesive feature in the landscape.	
Magnitude of Change	High → Medium → Low → Negligible		

Significance of Effects on Landscape Character Receptors

- 5.5.17 The significance of the effect on each landscape character receptor is dependent on all of the factors considered in the sensitivity of the receptor, and the magnitude of change resulting from the Proposed Scheme. These judgements on sensitivity and magnitude are combined to arrive at an overall assessment as to whether the Proposed Scheme would have an effect that is significant or not significant on the landscape character receptor. An assessment of the factors considered in the evaluation of the sensitivity of each landscape character receptor and the magnitude of the change resulting from the Proposed Scheme are presented in the assessment in order that the relevant considerations which have informed the significance can be considered transparently. The matrix shown in Table 6.1.1 helps to inform the threshold of significance when combining sensitivity and magnitude to assess significance.
- 5.5.18 A significant effect would occur where the combination of the variables results in the Proposed Scheme having a defining effect on the landscape character receptor, or where changes of a lower magnitude occur on a landscape character receptor that is of particularly high sensitivity. A not significant effect would occur where the effect of the

Proposed Scheme is not definitive, and the landscape character of the receptor continues to be characterised principally by its baseline characteristics, or where the small scale of change experienced by a high sensitivity receptor is such as to be considered not significant. A major loss or irreversible effect over an extensive area, on elements and/or perceptual aspects that are key to the character of nationally valued landscapes are likely to be of greatest significance. Reversible effects, over a restricted area, on elements and/or perceptual aspects that contribute to but are not key characteristics of the character of landscapes that are of lower value, are likely to be of least significance.

- 5.5.19 OPEN has chosen to keep the consideration of the size or scale of the effect, its geographical extent and its duration and reversibility separate, by basing the magnitude of change on size or scale to determine where significant and not significant effects occur, and then describing the geographical extents of these effects and their duration and reversibility separately. Duration and reversibility are therefore stated separately in relation to the assessed effects (i.e. as short/medium/long-term and temporary/permanent) and are considered as part of drawing conclusions about significance, combining with other judgements on sensitivity and magnitude, to allow a final judgement to be made on whether each effect is significant or not significant.

5.6 Assessment of Visual Effects

- 5.6.1 The assessment of visual effects is an assessment of how the introduction of the Proposed Scheme would affect the views available to people and their visual amenity. The assessment of visual effects is carried out in two parts:
- an assessment of the effects that the Proposed Scheme would have on a series of viewpoints that have been selected to represent the views available to people from representative or specific locations within the Study Area; and
 - an assessment of the effects that the Proposed Scheme would have from principal visual receptors, including residents of settlements, motorists using roads and people using recreational routes, features and attractions throughout the Study Area.
- 5.6.2 The objective of the assessment of effects on visual receptors is to determine what the likely effects of the Proposed Scheme would be on the people experiencing views across the Study Area, and whether these effects would be significant or not significant. The methodology for the assessment of visual effects involves the undertaking of a baseline study, evaluation of sensitivity, magnitude of change and an assessment of significance.

Visual Baseline and Scope Assessment

- 5.6.3 The visual baseline establishes the area in which the Proposed Scheme may be visible, the different groups of people who may experience views of the Proposed Scheme, the viewpoints where they would be affected and the nature of the views at those points. The visual baseline describes aspects of the visual amenity that may be significantly affected, as defined in Schedule 4 of the EIA Regulations. The baseline description of the groups of people (referred to as visual receptors) and viewpoints that may be affected is primarily determined by the ZTV.
- 5.6.4 An overview of the visual baseline is described, and a scope assessment identifies visual receptors that may experience significant effects, which require to be assessed in full. A full description of the baseline is provided for each visual receptor that may experience

significant effects, allowing the full baseline to be described for visual receptors that may be significantly affected. Those receptors which are identified as not having the potential to undergo significant effects are not included in the subsequent detailed assessment but are noted with reasons given for their exclusion.

5.6.5 The baseline study establishes the visual baseline, including the area from which the Proposed Scheme may be visible, the different groups of people who may experience views of the Proposed Scheme (visual receptors), the viewpoints where they would be affected and nature of views at these points. The baseline study establishes the visual baseline in relation to the following matters:

- the area from which the Proposed Scheme may be visible, that is land from which it may potentially be seen, is established and mapped using an initial ZTV of the Proposed Scheme;
- the location, type and number of visual receptors experiencing visibility of the Proposed Scheme, the likely views experienced and the activity / occupation they are engaged in;
- selection of viewpoints from within the ZTV, including representative viewpoints selected to represent the experience of different types of visual receptor and specific viewpoints selected because they are key/promoted viewpoints in the landscape;
- the location, character and type of each viewpoint with an indication of the type of visual receptor likely to be experiencing the view from each viewpoint;
- the nature of the view in terms of both the direction of view towards the Proposed Scheme as well as the wider available view, making reference to the principal orientation, focal features, and visible extents in terms of both horizontal degrees and distance;
- the character of the view in terms of its content and composition, its horizontal and vertical scale as well as depth and sense of perspective, important attributes such as prominent skylines and focal points and ultimately identifying the defining patterns and features which characterise the view; and
- the influence of human intervention and how the addition of artefacts and modification through land use affect the baseline situation. This may include operational windfarms where they are a feature of the baseline visual context.

5.6.6 The visual baseline also describes current pressures that may cause change to the visual amenity of the area in the future, in particular drawing on information for wind energy developments that are not yet present in the landscape but are at other stages in the project and consenting process. Operational and under construction wind energy developments are regarded as part of the baseline visual context. Any changes resulting from the Proposed Scheme are assessed within this context in the assessment of landscape and visual effects.

Sensitivity of Visual Receptors

5.6.7 The sensitivity of visual receptors is determined by a combination of the value of the view and the susceptibility of the visual receptors to the change that the Proposed Scheme would have on the view.

Value of the View

5.6.8 The value of a view or series of views is a reflection of the recognition and the importance attached either formally through identification on mapping or being subject to planning designations, or informally through the value which society attaches to the view(s). The value of a view is classified as high, medium-high, medium, medium-low or low and the basis for this assessment is made clear using evidence and professional judgement, based on the following criteria:

- Formal recognition: The value of views can be formally recognised through their identification on OS or tourist maps as formal viewpoints, sign-posted and with facilities provided to add to the enjoyment of the viewpoint such as parking, seating and interpretation boards. Specific views may be afforded protection in local planning policy and recognised as valued views. Specific views can also be cited as being of importance in relation to landscape or heritage planning designations, for example the value of a view would be increased if it presents an important vista from a designed landscape or lies within or overlooks a designated area such as a National Scenic Area, which implies a greater value to the visible landscape.
- Informal recognition: Views that are well-known at a local level can have an increased value, even if there is no formal recognition or designation. Views or viewpoints are sometimes informally recognised through references in art or literature and this can also add to their value. A viewpoint that is visited or used by a large number of people would tend to have greater importance than one gained by very few people, although this is not always the case.

Susceptibility to Change

5.6.9 Susceptibility relates to the nature of the viewer experiencing the view and how susceptible they are to the potential effects of the Proposed Scheme. A judgement to determine the level of susceptibility therefore relates to the nature of the viewer and their experience from that particular viewpoint or series of viewpoints, as follows:

- Nature of the viewer: The nature of the viewer is described by the occupation or activity which they are engaged in at the viewpoint or series of viewpoints. The most common groups of viewers considered in the visual assessment include residents, road-users, workers and walkers. Viewers whose attention is focused on the landscape, walkers, for example are likely to have a higher sensitivity, as would residents of properties that gain constant views of the Proposed Scheme. Viewers travelling in cars or on trains would tend to have a lower sensitivity as their view is transient and moving. The least sensitive viewers are usually people at their place of work as they are less sensitive to changes in the view; however, this also depends on the nature of their work and the work place which they occupy.
- Experience of the viewer: The experience of the visual receptor relates to the extent to which the viewer's attention or interest may be focused on the view and the visual amenity they experience at a particular location. The susceptibility of the viewer to change arising from the Proposed Scheme may be influenced by the viewer's attention or interest in the view, which may be focused in a particular direction, from a static or transitory position, over a long or short duration, and with high or low clarity. For example, if the principal outlook from a route is aligned directly towards the Proposed Scheme, the experience of the visual receptor would be altered more notably than if the experience related to a glimpsed view seen at an oblique angle from a car travelling at high speed. The visual amenity experienced by the viewer varies depending on the presence and relationship of visible elements, features or patterns experienced in the view and the degree to

which the landscape in the view may accommodate the influence of the Proposed Scheme.

Sensitivity Rating

- 5.6.10 An overall level of sensitivity is applied for each visual receptor or view: high, medium-high, medium, medium-low, low; by combining individual assessments of the value of the receptor and its susceptibility to change. Each visual receptor, meaning the particular person or group of people likely to be affected at a specific viewpoint, is assessed in terms of their sensitivity. The basis for the assessments is made clear using evidence and professional judgement in the evaluation of each receptor. Criteria that tend towards higher or lower sensitivity are set out in Table 5.1.4.

Table 5.1.4: Sensitivity to Change – Visual Receptors

Criteria tending towards higher or lower sensitivity		
	High →	Medium → Low
Value	Specific viewpoint identified in OS maps and/or tourist information and signage. Facilities provided at viewpoint to aid the enjoyment of the view. View afforded protection in planning policy. View is within or overlooks a designated landscape, which implies a higher value to the visible landscape. View has informal recognition and well-known at a local level. View or viewpoint is recognised through references in art or literature.	Viewpoint not identified in OS maps or tourist information and signage. No facilities provided at viewpoint to aid enjoyment of the view. View is not afforded protection in planning policy. View is not within, nor does it or overlook, a designated landscape. View has no informal recognition. View or viewpoint is not characteristic through references in art or literature.
Susceptibility to Change	Viewer whom is likely or liable to be influenced by the Proposed Scheme. Viewers such as walkers, or tourists, whose main attention and interest is on their surroundings. Residents that gain static, long-term views of the Proposed Scheme in their principal outlook. Viewpoint is visited or used by a large number of people. A view that is focused in a specific directional vista, with notable features of interest in a particular part of the view. A view of an undeveloped landscape with little or no built development and/or human influence.	Viewer whom is unlikely or not liable to be influenced by the Proposed Scheme. Viewers whose main attention is not focused on their surroundings, such as people at work, or specific forms of recreation. Viewers whom are transient and dynamic, such as those travelling in cars or on trains, where the view is of short duration. View is visited or gained by very few people. Open views with no specific point of interest. A view of a developed, industrial landscape where built elements and structures are present. Existing elements, features or patterns in view that may assist with integration of the Proposed Scheme.

	Existing elements, features or patterns in view that would contrast with the Proposed Scheme.	
Sensitivity to Change	High  Medium  Low	

Magnitude of Change on Views

- 5.6.11 The magnitude of change on views is an expression of the scale of the change that would result from the Proposed Scheme and is dependent on a number of variables regarding the size or scale of the change. A separate assessment is also made of the geographical extent of the area over which this would occur and the duration and reversibility of such changes.

Size or Scale

- 5.6.12 An assessment is made about the size or scale of change in the view that is likely to be experienced as a result of the Proposed Scheme, based on the following criteria:
- The distance between the visual receptor or viewpoint and the Proposed Scheme. Generally, the greater the distance, the lower the magnitude of change, as the Proposed Scheme would constitute a smaller scale component of the view;
 - The amount and size of the Proposed Scheme that would be seen. Visibility may range from one blade tip to all of the turbines. Generally, the larger the Proposed Scheme appears in the view, and the more of the Proposed Scheme that can be seen, the higher the magnitude of change;
 - The scale of the change in the view, with respect to the loss or addition of features in the view and changes in its composition. The Proposed Scheme may appear in a similar part of the view to that which includes an operational windfarm or it may appear close to or as an extension to an existing windfarm and its scale of change is assessed in the context of these existing views;
 - The field of view available and the proportion of the view that is affected by the Proposed Scheme. Generally, the more of a view that is affected, the higher the magnitude of change would be. If the Proposed Scheme extends across the whole of the open part of the outlook, the magnitude of change would generally be higher as the full view would be affected; Conversely, if the Proposed Scheme covers just a part of an open, expansive and wide view, the magnitude of change is likely to be reduced as the Proposed Scheme would not affect the whole open part of the outlook;
 - The scale and character of the context within which the Proposed Scheme would be seen and the degree of contrast or integration of any new features with existing landscape elements, in terms of scale, form, mass, line, height, colour and motion. Contrasts and changes may arise particularly as a result of the more notable rotation movement of the wind turbine blades, as a characteristic that gives rise to effects of the Proposed Scheme;
 - The consistency of image of the Proposed Scheme in relation to other developments. The magnitude of change of the Proposed Scheme is likely to be lower if its wind turbine height, arrangement and layout design are broadly similar to other windfarm developments in the views, as they are more likely to appear as relatively simple and logical components of the landscape;
 - The uniformity of appearance of the Proposed Scheme in different views. If the Proposed Scheme appears relatively uniform and consistent in appearance from different viewpoints and viewing angles, in a similar setting and familiar form, this

tends to reduce the magnitude of change. If, on the other hand, it appears inconsistent in image, scale and appearance, or from a variety of different angles, and is seen in a different form and setting, the magnitude of change is likely to be higher as it would be a variable and less familiar component of views;

- The extent of the wind energy developed skyline. If the Proposed Scheme would add notably to the wind energy developed skyline in a view, extending the lateral spread of development or increasing the perceived connection between other windfarms, the magnitude of change would tend to be higher;
- The number and scale of developments seen simultaneously or sequentially. Generally, the greater the number of clearly separate developments that are visible, the higher the magnitude of change would be, whereas an extension to an existing windfarm would tend to result in a lower magnitude of change than a separate, new windfarm; and
- The scale and form comparison between developments. If the Proposed Scheme is of a similar scale and form to other visible developments, particularly those seen in closest proximity to it, the magnitude of change would generally be lower as it would have more integration with the other sites and would be less apparent as an addition.

Geographical Extent

- 5.6.13 The geographic area over which the visual effects would be experienced is also assessed, which is distinct from the size or scale of effect. The extent of the effects would vary depending on the specific nature of the Proposed Scheme and is principally assessed through analysis of the extent of visibility of the Proposed Scheme from visual receptors, to assess the geographical extent of the receptor that would be affected, based on the following criteria:
- 5.6.14 The extent of the visual receptor (a road, footpath or settlement for example) that would experience changes through visibility of the Proposed Scheme. If the Proposed Scheme is visible from extensive areas, the overall change is likely to be higher than if it is visible from a limited part of a receptor. The extent to which the change would affect views, whether this is unique to a particular viewpoint or if similar visual changes occur over a wider area represented by the viewpoint.

Magnitude of Change Rating

- 5.6.15 An overall assessment of the magnitude of change resulting from the Proposed Scheme on each visual receptor is made by combining the assessment of size or scale and geographical extent. The basis of the assessment is made clear using evidence and professional judgement. The levels of magnitude of change that can occur on views are defined as follows:
- High: the Proposed Scheme would result in a major alteration to the baseline view, providing the prevailing influence and/or introducing elements that are substantially uncharacteristic in the receiving view;
 - Medium: the Proposed Scheme would result in a moderate alteration to the baseline view, providing a readily apparent influence and/or introducing elements potentially uncharacteristic in the receiving view;
 - Low: the Proposed Scheme would result in a minor alteration to the baseline view, providing a slightly apparent influence and/or introducing elements that are characteristic in the receiving view;

- Negligible: the Proposed Scheme would result in a negligible alteration to the baseline view, providing a barely discernible influence and/or introducing elements that are substantially characteristic in the receiving view; and
- None: the Proposed Scheme would in no way change to the baseline characteristics of the view.

5.6.16 There may also be intermediate levels of magnitude of change, such as medium-high or medium-low, where the change falls between the definitions. Criteria that tend towards higher or lower magnitude of change are set out in Table 5.1.5.

Table 5.1.5: Magnitude to Change Criteria – Visual Receptors

Criteria tending towards higher or lower magnitude		
	High —————> Medium —————> Low —————> Negligible	
Size or scale of change	Large scale change in the view resulting from loss and/or addition of features and changes in its composition. Proposed Scheme located in close proximity to the viewpoint and would form large scale component of the view. All or majority of the Proposed Scheme would be visible in the view e.g. full towers and rotor sweep. Proposed Scheme effects large proportion of available field of view. Proposed Scheme has high degree of contrast/low degree of integration with existing landscape elements, in terms of scale, form, mass, line, height, colour and texture. Proposed Scheme appears inconsistently, in a different setting and/or form each time it is visible. Proposed Scheme contrasts with other existing windfarms in pattern, scale and relationship to key characteristics, creating a confusing or inconsistent image or relationship to key characteristics.	Small scale change in the view resulting from loss and/or addition of features and changes in its composition. Proposed Scheme located at long distance from the viewpoint and would form small scale component of the view. Limited amount of the Proposed Scheme would be visible in the view e.g. extremity of blade tips. Proposed Scheme effects small proportion of available field of view. Proposed Scheme has low degree of contrast/high degree of integration with existing landscape elements, in terms of scale, form, mass, line, height, colour and texture. Proposed Scheme appears consistent, in a similar setting and/or form each time it is visible. Proposed Scheme consolidates existing windfarms, relates consistently to a key characteristic of the landscape and/or has a high level of integration forming a unified and cohesive feature in the landscape.
Geographical Extent	Extensive / long distance —————> Scattered / mid-range —————> Limited / short distance	
	Proposed Scheme is visible over long distances. Proposed Scheme is visible from widespread areas/extensive parts of visual receptor. Visibility/views of Proposed Scheme occur over a wider area represented by multiple viewpoints.	Proposed Scheme is visible only at short range. Proposed Scheme is visible from restricted areas/limited parts of visual receptor. Visibility/view of Proposed Scheme is unique to a particular location or viewpoint.
Magnitude of Change	High —————> Medium —————> Low —————> Negligible	

Significance of Effects on Views

- 5.6.17 The significance of the effect on each view is dependent on all of the factors considered in the sensitivity of the view, and the magnitude of change resulting from the Proposed Scheme. These judgements on sensitivity and magnitude are combined to arrive at an overall assessment as to whether the Proposed Scheme would have an effect that is significant or not significant on the visual receptor.
- 5.6.18 Table 5.1.1 helps to inform the threshold of significance when combining sensitivity and magnitude to assess the significance of effect.
- 5.6.19 A significant effect would occur where the combination of the variables results in the Proposed Scheme having a defining effect on the view or where changes of a lower magnitude occur on a view or visual receptor that is of particularly high sensitivity. A not significant effect would occur where the appearance of the Proposed Scheme is not definitive, and the view continues to be defined principally by its baseline characteristics or where the small scale of change experienced by a high sensitivity receptor is such as to be considered not significant. Irreversible, long-term effects on people who are particularly sensitive to changes in views and visual amenity are more likely to be significant, as are effects on people at recognised viewpoints. Large-scale changes which introduce new, non-characteristic or discordant elements into the view are also more likely to be significant than small changes or changes involving features already present within the view.
- 5.6.20 OPEN has chosen to keep the consideration of the size or scale of the effect, its geographical extent and its duration and reversibility separate, by basing the magnitude of change on size or scale to determine where significant and not significant effects occur, and then describing the geographical extents of these effects and their duration and reversibility separately. Duration and reversibility are therefore stated separately in relation to the assessed effects (i.e. as short/medium/long-term and temporary/permanent) and are considered as part of drawing conclusions about significance, combining with other judgements on sensitivity and magnitude, to allow a final judgement to be made on whether each effect is significant or not significant.
- 5.6.21 The assessment of visual effects assumes clear weather and optimum viewing conditions. This means that effects that are assessed to be significant may be not significant under different, less clear conditions. Viewing conditions and visibility tend to vary considerably and therefore the likelihood of effects resulting from the Proposed Scheme would vary greatly dependent according to the prevailing viewing conditions.

5.7 Nature of Effects

- 5.7.1 The nature of effects refers to whether the landscape and/or visual effect of the Proposed Scheme is positive or negative (herein referred to as 'beneficial' and 'adverse').
- 5.7.2 Guidance provided by the Landscape Institute on the nature of effect in GLVIA3 states that "in the LVIA, thought must be given to whether the likely significant landscape and visual effects are judged to be positive (beneficial) or negative (adverse) in their consequences for landscape or for views and visual amenity", but it does not provide guidance as to how that may be established in practice. The nature of effect is therefore one that requires interpretation and, where applied, this involves reasoned professional opinion.

- 5.7.3 In relation to many forms of development, the LVIA will identify 'beneficial' and 'adverse' effects by assessing these under the term 'Nature of Effect'. The landscape and visual effects of windfarms are difficult to categorise in either of these brackets as, unlike other disciplines, there are no definitive criteria by which the effects of windfarms can be measured as being categorically 'beneficial' or 'adverse'. In some disciplines, such as noise or ecology, it is possible to quantify the effect of a windfarm in numeric terms, by objectively identifying or quantifying the proportion of a receptor that is affected by the Proposed Scheme and assessing the nature of that effect in justifiable terms. However, this is not the case in relation to landscape and visual effects where the approach combines quantitative and qualitative assessment.
- 5.7.4 Generally, in the development of 'new' wind farms, a precautionary approach is adopted by OPEN, which assumes that significant landscape and visual effects will be weighed on the adverse side of the planning balance. Unless it is stated otherwise, the effects considered in this assessment are considered to be adverse. Beneficial or neutral effects may, however, arise in certain situations and are stated in the assessment where relevant, based on the following definitions:
- 5.7.5 Beneficial effects contribute to the landscape and visual resource through the enhancement of desirable characteristics or the introduction of new, beneficial attributes. The Proposed Scheme contributes to the landscape by virtue of good design, even if it contrasts with the existing character. The removal of undesirable existing elements or characteristics can also be beneficial, as can their replacement with more appropriate components;
- 5.7.6 Neutral effects occur where the Proposed Scheme fits with the existing landscape character or visual amenity. The Proposed Scheme neither contributes to nor detracts from the landscape and visual resource and can be accommodated with neither beneficial or adverse effects, or where the effects are so limited that the change is hardly noticeable. A change to the landscape and visual resource is not considered to be adverse simply because it constitutes an alteration to the existing situation; and
- 5.7.7 Adverse effects are those that detract from the landscape character or quality of visual attributes experienced, through the introduction of elements that contrast, in a detrimental way, with the existing characteristics of the landscape and visual resource, or through the removal of elements that are key in its characterisation.

5.8 Duration and Reversibility

- 5.8.1 The EIA Regulations (2017) require a description of the likely significant effects on factors including (among other things) 'short-term, medium-term and long-term, permanent and temporary effects'.
- 5.8.2 Duration (short, medium or long-term) and reversibility (permanent or temporary) are separate but linked considerations. Duration of effects are judged on a scale as long-term, medium-term and short-term effects, defined in this methodology as follows:
- Long-term – more than 10 years;
 - Medium-term – 5 to 10 years.
 - Short-term – 1 to 4 years.

- 5.8.3 Reversibility is a judgement about the degree of permanence or temporary nature of an effect, determined by the prospects and the practicality of the particular effect being reversed and the time period over which this may occur. Some forms of development can be considered permanent, while others can be considered temporary or reversible since they have a limited operational life and would be removed and/or the land reinstated.
- 5.8.4 The effect of the Proposed Scheme is considered to be long term and reversible, in that the wind turbines and infrastructure can be removed and their effects largely reversed at the end of the 35 year operational period.
- 5.8.5 The effect of the construction of the Proposed Scheme is assessed as temporary and short-term in this LVIA. Other infrastructure and operations such as the construction processes and plant (including tall cranes and heavy machinery for turbine erection) and construction and storage compounds would be apparent only during the initial construction period of the Proposed Scheme and are assessed as short-term and reversible effects. Borrow pit excavation would also be short-term as borrow pits would be restored at the end of the construction process, although a permanently altered ground profile may remain evident.
- 5.8.6 GLVIA3 sets out an approach to the assessment of magnitude of change in which three separate considerations are combined within the magnitude of change rating. These are the size or scale of the effect, its geographical extent and its duration and reversibility. OPEN considers that the process of combining all three considerations in one magnitude of change rating can distort the aim of identifying significant effects of wind farm development. For example, an increased magnitude of change, based on size or scale, may be reduced to a lower rating if it occurred over a localised geographic extent and for a short duration. This might mean that a potentially significant effect would be overlooked if effects are diluted down due to their geographical extents and/or duration or reversibility.
- 5.8.7 OPEN has chosen to keep these the consideration of the size or scale of the effect, its geographical extent and its duration and reversibility separate, by basing the magnitude of change on size or scale to determine where significant and not significant effects occur, and then describing the geographical extents of these effects and their duration and reversibility separately. Duration and reversibility are therefore stated separately in relation to the assessed effects (i.e. as short/medium/long-term and temporary/permanent) and are considered as part of drawing conclusions about significance, combining with other judgements on sensitivity and magnitude, to allow a final judgement to be made on whether each effect is significant or not significant.
- 5.8.8 Should decommissioning of any part of the Proposed Scheme be required e.g. failure of a wind turbine beyond economic repair, it is considered that any effects would be less than those resulting from construction of the Proposed Scheme, and as such this potential for decommissioning has been scoped out of further assessment.

5.9 Assessment of Cumulative Landscape and Visual Effects

Introduction

- 5.9.1 Assessment of cumulative effects is required by the EIA Regulations. Cumulative effects have been defined in a broad generic sense as *"impacts that result from incremental changes caused by other past, present or reasonably foreseeable actions together with the project"* (Hyder, 1999, p7).
- 5.9.2 In GLVIA3 (Landscape Institute and IEMA, 2013, p120) the guidelines define cumulative landscape and visual effects as those that *"result from additional changes to the landscape and visual amenity caused by the Proposed Scheme in conjunction with other developments (associated with or separate to it), or actions that occurred in the past, present or are likely to occur in the foreseeable future."*
- 5.9.3 NatureScot's guidance, 'Assessing the Cumulative Impact of Onshore Wind Energy Developments' (2021) is widely used across the UK to inform the specific assessment of the cumulative effects of wind farms. This guidance provides the basis for the methodology for the cumulative assessment.
- 5.9.4 The guidance defines the following types of cumulative effects:
- 'Cumulative impacts can change either the physical fabric or character of the landscape, or any special values attached to it' (NatureScot 2021, p7); and
 - 'Cumulative impacts on visual amenity can be caused by 'combined visibility' and/or 'sequential impacts'.' (NatureScot 2021, p7).
- 5.9.5 The degree to which cumulative effects occur, or may occur, as a result of more than one wind farm/development being constructed/becoming operational are a result of:
- the distance between individual wind farms/relevant developments;
 - the interrelationship between their ZTVs;
 - the overall character of the landscape and its sensitivity to wind farms/other relevant development;
 - the siting, scale and design of the wind farms/developments themselves; and
 - the way in which the landscape is experienced.

Scope of the Cumulative Assessment

- 5.9.6 NatureScot's guidance highlights that *'The purpose of a Cumulative Landscape and Visual Impact Assessment (CLVIA) is to describe, visually represent and assess the ways in which a proposed wind farm would have additional impacts when considered with other consented or proposed wind farms. It should identify the significant cumulative impacts arising from the proposed wind farm.'* GLVIA3, p120 also highlights that *'the focus of the cumulative assessment will be on the additional effect of the project in conjunction with other developments of the same type (as for example, in the case of wind farms)'*
- 5.9.7 In accordance with the aforementioned guidance, the cumulative assessment focuses on the addition of the Proposed Scheme to other wind farm development. Wind energy development data was sourced directly from relevant local authorities, a range of wind energy developer web sites and local authority online planning application portals. The cumulative assessment includes all wind turbine developments that are operational, under construction, consented or at planning application stage and are over 50 m to tip

in height. It is considered that turbines below 50 m in height are unlikely to result in significant cumulative effects with the Proposed Scheme.

- 5.9.8 However, in line with advice provided by the Planning Inspectorate in the scoping direction, other forms of major development have also been considered to determine whether or not they could potentially lead to a significant cumulative effect when considering landscape or visual interaction with the Proposed Scheme.
- 5.9.9 The extent of detailed cumulative assessment within this area is then defined relative to key landscape and visual receptors and anticipated effects, focussing on potential significant cumulative effects, and refining to a list of projects to those within 'influencing distance'.
- 5.9.10 NatureScots guidance highlights that '*The assessment should be proportionate to the likely impacts and all CLVIA should accord with the guidelines within GLVIA3. The emphasis should be on the production of relevant and useful information, highlighting why the proposals assessed have been included and why others have been excluded, rather than the provision of a large volume of information.*' (NatureScot 2021, p8).
- 5.9.11 The cumulative assessment therefore focuses on identifying cumulative effects which are likely to be a key consideration in determining the application, rather than an assessment of every potential cumulative effect.
- 5.9.12 A comprehensive list of cumulative developments has been compiled and this 'long list' and the approach to compiling this list is described in Volume 2 Chapter 13. In line with the above scope the cumulative search area for the LVIA includes the following search criteria –
- Wind turbine development above 50m in height to a distance of 45km from the Proposed Scheme
 - Other national infrastructure developments to a distance of 45km from the Proposed Scheme
 - Local developments to a distance of 10km from the Proposed Scheme
- 5.9.13 The cumulative situation changes frequently as applications are made or withdrawn, and the layouts of submitted application wind farms are changed. It is therefore necessary to decide on a cut-off date when the sites and layouts to be included are fixed. The cumulative assessment includes non-wind cumulative developments as of September 2022 (and updated in January 2023 following PAC comments) and wind energy developments as of March 2023. Any changes in the cumulative situation after this date are not incorporated in the assessment.

Cumulative Development Scenarios

- 5.9.14 GLVIA3 (Landscape Institute and IEMA, 2013, p120) advises in relation to the baseline, taking 'the Proposed Scheme' to mean the main proposal that is being assessed, "*it is considered that existing schemes and those which are under construction should be included in the baseline for both landscape and visual effects assessments (the LVIA baseline). The baseline for assessing cumulative landscape and visual effects should then include those schemes considered in the LVIA and in addition potential schemes that are not yet present in the landscape but are at various stages in the development and consenting process*". The LVIA follows this approach and the cumulative effects that would potentially arise from the addition of the Proposed Scheme into a context that

includes existing or under construction wind farms are assessed, with the effects considered against the landscape and visual baseline.

- 5.9.15 In terms of the timescale of proposals for inclusion, both NatureScot guidance and GLVIA3 advise in their guidance that the assessment of the cumulative impacts associated with the Proposed Scheme should encompass the effects of the proposal in combination with existing, under construction, consented and application stage wind farms awaiting determination.
- 5.9.16 Schemes that are at the pre-planning or scoping stage are typically not considered in the assessment of cumulative effects due to layout and design uncertainties at the pre-application stages and as such firm information on which to base the assessment of this scenario is not available. However, in response to PAC comments made by BBNPA in relation to the emerging pattern of development to the south of the BBNP, an assessment of the scoping scenario is also included in the LVIA.
- 5.9.17 The likely significant cumulative effects of the Proposed Scheme are assessed in relation to three scenarios within the cumulative assessment:
- **The consented scenario:** the cumulative assessment assesses the effect of the Proposed Scheme in addition to wind farms already present in the landscape (operational/under construction wind farms) and wind farms that are likely to soon be present (consented wind farms) ('the consented scenario'). This scenario assumes that all consented wind energy developments have become operational and are part of a theoretical baseline situation. The cumulative assessment in the consented scenario identifies the magnitude of change that would arise due to the contribution of the Proposed Scheme, when considered with operational, under construction and consented wind energy developments in the landscape. The effects identified are considered as having some likelihood to arise, on the assumption that consented wind farms will be built and become operational, however it is often the case that consented wind farms are not ultimately built, which reduces the likelihood of consented scenario effects arising.
 - **The application scenario:** a further hypothetical scenario is also assessed, that not only takes into the account the operational, under construction and consented wind farms, but also those that have valid (but as yet underdetermined) planning applications ('the application scenario'). The application scenario assumes that all application wind energy developments have become operational and are part of a theoretical baseline situation. The cumulative assessment in the application scenario identifies the magnitude of additional cumulative change that would arise due to the contribution of the Proposed Scheme, when considered with operational, consented and application stage wind energy developments in the landscape. The effects identified are considered as being less likely to arise, as it is unlikely that all application wind farms will gain consent.
 - **The scoping scenario:** similar to the application scenario, a further hypothetical scenario is also assessed, that not only takes into the account the operational, under construction, consented and application wind farms, but also those sites that are at scoping stage ('the scoping scenario'). The scoping scenario assumes that all scoping wind energy developments have become operational and are part of a theoretical baseline situation. The cumulative assessment in the scoping scenario identifies the magnitude of additional cumulative change that would arise due to the contribution of the Proposed Scheme, when considered with operational, consented, application and scoping wind energy developments in the landscape. The effects identified are considered as being far less likely to arise, as it is unlikely that all application and scoping wind farms will gain consent.

- 5.9.18 Regarding cumulative advice provided by the Planning Inspectorate in the scoping direction, relating to Advice Note 17: Cumulative Effects Assessment guidance for Nationally Significant Infrastructure Projects (NSIPs), the consented and application scenarios considered in the LVIA fall within Tier 1 and the scoping scenario falls within Tier 2.

Types of Cumulative Effect

- 5.9.19 The aim of the cumulative assessment is to identify the additional changes which would be brought about by the Proposed Scheme when considered in conjunction with other wind farms. In accordance with guidance (NatureScot, 2021), the LVIA for each receptor considered assesses the effect arising from the addition of the Proposed Scheme to the cumulative situation, and not the overall effect of multiple wind farms. Adjacent developments may complement one another, or may be discordant with one another, and it is the increased or reduced level of significance of effects which arises as a result of this change that is assessed in the cumulative assessment.

Cumulative Landscape Effects

- 5.9.20 The cumulative development of wind farms within a particular area may build up to create different types of landscape. Significant cumulative landscape effects may arise where a '*Landscape with wind farms*' is created, as a result of the addition of the Proposed Scheme to other existing or proposed wind farms, which results in wind turbines becoming sufficiently prolific that they become a prevailing or key landscape and visual characteristic.
- 5.9.21 The significance of the cumulative landscape effect from the addition of the Proposed Scheme reflects the intensification of wind farms within the landscape, which is assessed as follows:
- The Proposed Scheme forms a separate isolated feature from other wind farms within the landscape, too infrequent and of insufficient influence to be perceived as a characteristic of the area. The cumulative landscape effect of the Proposed Scheme is unlikely to be significant;
 - The addition of the Proposed Scheme results in wind farms forming a key characteristic of the landscape, exerting sufficient presence as to establish or increase the extent of a 'landscape with wind farms', but not of sufficient dominance to be a defining characteristic of the area. The cumulative landscape effect of the Proposed Scheme may be significant or not significant, depending on the sensitivity of the receptor, magnitude of the change and specific effects arising from the Proposed Scheme; and
 - The addition of the Proposed Scheme results in wind farms forming the prevailing characteristic of the landscape, seeming to define the landscape as a 'wind farm landscape' character type. The cumulative landscape effect of the Proposed Scheme is likely to be significant.
- 5.9.22 These effects can occur at varying scales, for example, effecting a local character type, or at a regional level, which is assessed as part of the geographic extent assessment in the LVIA.

Cumulative Visual Effects

- 5.9.23 Cumulative visual effects consist of combined and sequential effects:

- Combined visibility occurs where the observer is able to see two or more developments from one viewpoint. Combined visibility may either be 'in combination', where several wind farms are within the observer's main angle of view at the same time, or 'in succession', where the observer has to turn to see the various wind farms. The cumulative visual effect of the Proposed Scheme may be significant or not significant depending on factors influencing the cumulative magnitude of change, such as the degree of integration and consistency of image with other wind farms in combined views; and the position of the development relative to other wind farms and the landscape context in successive views.
- Sequential visibility occurs when the observer has to move to another viewpoint to see different developments. Sequential effects are assessed along regularly used routes such as major roads, railway lines and footpaths. The occurrence of sequential effects range from 'frequently sequential' (the features appear regularly and with short time lapses between, depending on speed of travel and distance between the viewpoints) to 'occasionally sequential' (long time lapses between appearances, because the observer is moving slowly and/or there are large distances between the viewpoints). The cumulative visual effect of the Proposed Scheme is more likely to be significant when frequently sequential.

5.9.24 The methodology for the assessment of cumulative landscape and visual effects involves the undertaking of a baseline study of the existing and potential future wind farm/other relevant development influence, an evaluation of sensitivity, magnitude of change and the resulting significance of cumulative effects.

Cumulative Sensitivity of Landscape and Visual Receptors

5.9.25 In evaluating cumulative sensitivity, the value component of the assessments of sensitivity would not change, however, in an evolving wind farm/other relevant development context, the susceptibility of a landscape and visual receptor to the introduction of the Proposed Scheme may increase or decrease. This is therefore re-evaluated based on the criteria contained in the landscape and visual susceptibility criteria sections of this methodology.

Cumulative Magnitude of Change

5.9.26 The cumulative magnitude of change is an expression of the degree to which landscape character receptors and visual receptors/views would be changed by the addition of the Proposed Scheme to wind farms/other relevant developments that are already operational, consented or at application stage. Where required, scoping stage wind farms and other early stage developments may exceptionally be included. The cumulative magnitude of change is assessed according to a number of criteria, described as follows:

- The location of the Proposed Scheme in relation to other wind farm developments. If the Proposed Scheme is seen in a part of the view or setting to a landscape receptor that is not affected by other development, this would generally increase the cumulative magnitude of change as it would extend influence into an area that is currently unaffected by development. Conversely, if the Proposed Scheme is seen in the context of other sites, the cumulative magnitude of change may be lower as development is not being extended to otherwise undeveloped parts of the outlook or setting. This is particularly true where the scale and layout of the Proposed Scheme is similar to that of the other sites as where there is a high level of integration and cohesion with an existing site the various developments may appear as a single site;

- The extent of the developed skyline. If the Proposed Scheme would add notably to the developed skyline in a view, the cumulative magnitude of change would tend to be higher as skyline development can have a particular influence on both views and landscape receptors;
- The number and scale of developments seen simultaneously or sequentially. Generally, the greater the number of clearly separate developments that are visible, the higher the cumulative magnitude of change would be. The addition of the Proposed Scheme to a view or landscape where a number of smaller developments are apparent would usually have a higher cumulative magnitude of change than one or two large developments as this can lead to the impression of a less co-ordinated or strategic approach;
- The scale comparison between developments. If the Proposed Scheme is of a similar scale to other visible developments, particularly those seen in closest proximity to it, the cumulative magnitude of change would generally be lower as it would have more integration with the other sites and would be less apparent as an addition to the cumulative situation;
- The consistency of image of the Proposed Scheme in relation to other developments. The cumulative magnitude of change of the Proposed Scheme is likely to be lower if its turbine height, arrangement and layout design are broadly similar to other developments in the landscape, as they are more likely to appear as relatively simple and logical components of the landscape;
- The context in which the developments are seen. If developments are seen in a similar landscape context, the cumulative magnitude of change is likely to be lower due to visual integration and cohesion between the sites. If developments are seen in a variety of different landscape settings, this can lead to a perception that wind farm development is unplanned and uncoordinated, affecting a wide range of landscape characters and blurring the distinction between them; and
- The magnitude of change of the Proposed Scheme as assessed in the main assessment. The lower this is assessed to be, the lower the cumulative magnitude of change is likely to be. Where the Proposed Scheme itself is assessed to have a negligible magnitude of change on a view or receptor there would not be a cumulative effect as the contribution of the Proposed Scheme would equate to the 'no change' situation.

5.9.27 Definitions of cumulative magnitude of change are applied in order that the process of assessment is made clear. These are:

- High: where the addition of the Proposed Scheme to the landscape or view would result in a major incremental change, loss or addition to the cumulative wind farm/development situation;
- Medium: where the addition of the Proposed Scheme would result in a moderate incremental change, loss or addition to the cumulative windfarm/development situation;
- Low: where the addition of the Proposed Scheme would result in a minor incremental change, loss or addition to the cumulative situation;
- Negligible: where the addition of the Proposed Scheme to other wind energy developments in the landscape or view would result in a negligible incremental change, loss or addition to the cumulative situation; and
- None: where the addition of the Proposed Scheme to other wind energy developments in the landscape or view would have no change to the cumulative windfarm situation and its addition equates to a 'no change' situation.

5.9.28 There may also be intermediate levels of cumulative magnitude of change: medium-high and medium-low; where the change falls between two of the definitions.

Significance of Cumulative Effects

- 5.9.29 The objective of the cumulative assessment is to determine whether any effects that the Proposed Scheme would have on landscape receptors and visual receptors, when seen or perceived in combination with other existing and proposed sites, would be significant or not significant. Significant cumulative landscape and visual effects arise where the addition of the proposed wind turbines or other similar/large scale development to a specific baseline, leads to windfarms becoming a prevailing landscape and visual characteristic of a receptor that is sensitive to such change. Cumulative effects may evolve as follows:
- A small scale, single windfarm would often be perceived as a new or 'one-off' landscape feature or landmark within the landscape. Except at a local site level, it usually cannot change the overall existing landscape character, or become a new characteristic element of a landscape;
 - With the addition of further windfarm development, windfarms can become a characteristic element of the landscape, as they appear as landscape elements or components that are repeated. Providing there was sufficient 'space' or undeveloped landscape/skyline between each windfarm, or the overlapping of several windfarms was not too dense; the Proposed Schemes or other similar/large scale developments would appear as a series of developments within the landscape and would not necessarily become the dominant or defining characteristic of the landscape nor have significant cumulative effects; and
 - The next stage would be to consider larger commercial windfarms/developments and/or an increase in the number of windfarms/developments within an area that either overlap or coalesce and/or 'join-up' along the skyline. The effect is to create a landscape where the windfarm element is a prevailing characteristic of the landscape. The result would be to materially change the existing landscape character of a landscape type, or the landscape in a view and resulting in a significant cumulative effect. A landscape characterised by windfarm development may already exist as part of the baseline landscape context.
- 5.9.30 Less extensive, but nevertheless significant cumulative landscape and visual effects may also arise as a result of the addition of the Proposed Scheme where it results in a landscape or view becoming defined by the presence of more than one wind farm or similar/large scale development, so that other patterns and components are no longer definitive, or where the Proposed Scheme contrasts with the scale or design of an existing or Proposed Scheme. Higher levels of significance may arise from cumulative landscape and visual effects related to the Proposed Scheme being in close proximity to other wind farms when they are clearly visible together in views, however provided that the Proposed Scheme is designed to achieve a high level of visual integration, with few notable visual differences between wind farms, these effects may not necessarily be significant. In particular, the effects of a wind farm extension are often less likely to be significant, where the effect is concentrated, providing that the design of the wind farms are compatible and that the overall capacity of the landscape is not exceeded.
- 5.9.31 The capacity of the landscape or view may be assessed as being exceeded where the landscape or visual receptor becomes defined by wind farm development, or if the Proposed Scheme extends across landscape character types or clear visual/topographic thresholds in a view. More substantial cumulative effects may result from wind farms that have some geographical separation, but remain highly inter-visible, potentially resulting in extending effects into new areas, such as an increased presence of wind farm

development on a skyline, or the creation of multiple, separate wind farm defined landscapes.

- 5.9.32 In accordance with guidance (NatureScot, 2021), the LVIA for each receptor considered assesses the effect arising from the addition of the Proposed Scheme to the cumulative situation, and not the overall effect of multiple windfarms.

5.10 Assessment of Lighting Effects

- 5.10.1 The Civil Aviation Authority (CAA) requires that 'en-route obstacles' at or above 150 m above ground level are lit with visible lighting to assist their detection by aircraft. As such, there is potential that parts of the Proposed Scheme may be visible at night. Specific requirements for aviation and navigational lighting would be agreed with the relevant stakeholders post-consent and prior to construction. The CAA requires that all obstacles at or above 150 m above ground level are fitted with visible lighting and in the case of wind turbines these should be located on the nacelle. There is an additional requirement for lights to be provided at an intermediate level of half the nacelle height. These would need to be fitted around the towers to allow for 360-degree horizontal visibility.
- 5.10.2 It should be noted that some turbines would include infra-red lighting on the turbine hubs, which would not be visible to the human eye. Details of the lighting would be agreed with the MoD. The focus of Appendix 5.5 is on the visible lighting requirements of the proposed Development. A description of the proposed turbine lighting is found within Chapter 4 Proposed Scheme and Chapter 12.1 Aviation, based on this, the assumptions and parameters for assessment of lighting effects have been made with regards to the LVIA.
- 5.10.3 GLVIA 3 (page 103) provides the following guidance on the assessment of lighting effects: *"For some types of development the visual effects of lighting may be an issue. In these cases it may be important to carry out night-time 'darkness' surveys of the existing conditions in order to assess the potential effects of lighting and these effects need to be taken into account in generating the 3D model of the scheme. Quantitative assessment of illumination levels, and incorporation into models relevant to visual effects assessment, will require input from lighting engineers, but the visual effects assessment will also need to include qualitative assessments of the effects of the predicted light levels on night-time visibility."*
- 5.10.4 The effect of the Proposed Scheme at night would result from visible lighting located on the nacelles, and on the towers, of all turbines. The LVIA assesses the visual effects of visible aviation lighting in Appendix 5.5 which includes specific lighting ZTVs and night time visualisations.
- 5.10.5 In terms of how lighting is captured in visualisations, the main change in the latest version of the NatureScot guidance "Visual Representation of Wind Farms" (Version 2.2, February 2017) is in paragraphs 174-177, which states: *"The visualisation should use photographs taken in low light conditions, preferably when other artificial lighting (such as street lights and lights on buildings) are on, to show how the wind farm lighting will look compared to the existing baseline at night"...* *"We have found that approximately 30 minutes after sunset provides a reasonable balance between visibility of the landform and the apparent brightness of artificial lights, as both should be visible in the image."* The night time photography has therefore been captured in low light conditions, when

other artificial lighting (such as street lights and lights on buildings) is on, to show how the windfarm lighting would look compared to the existing baseline at night.

- 5.10.6 Existing lights shown in the night time baseline photographs can appear larger and more blurred than those seen to the naked eye in the field when the photographs were captured. The term used in photography to describe this effect is 'Bokeh' which has been defined as 'the way the lens renders out-of-focus points of light'. This has proved difficult to avoid when taking photographs of light at varied distances across a view. The blurred nature of the lights is also exacerbated by their movement, particularly on vehicle headlights. Where the lights of the proposed Development have been added to the night time views this effect has been emulated. The lights that encircle communication masts are also blurred together creating a series of combined but brighter lights when viewed at distance.
- 5.10.7 The turbine blades, when they intermittently pass in front of the aviation lights, would cause randomised flickering when the lights are switched 'on'. The turbines used in the night time visualisations have been positioned so that their blades face away from the viewpoint so that all the lights are visible and on within the visualisations, representing a worst-case impression. The flickering effect caused by the blades interacting with the lights would be most usually apparent from a south westerly direction due to the prevailing south westerly wind.
- 5.10.8 The lighting represented in the viewpoint visualisations has been calibrated using examples of existing, equivalent, turbine lighting observed in the field in other parts of the UK, during similar periods of dusk / darkness as captured in the photography for the agreed viewpoints. For the assessment of lighting effects, the visual sensitivity and magnitude criteria described earlier in this Technical Appendix (TA: 6.1) has been applied.

5.11 Visual Representations

Zone of Theoretical Visibility (ZTV)

- 5.11.1 The ZTVs have been generated using Geographic Information System (GIS) software (ESRI ArcGIS Version 10.7.1) to demonstrate the number of turbines that may theoretically be seen from any point in the Study Area. The ZTVs, show the number of turbines (blade tips) that are theoretically visible around the Study Area (based on the maximum blade tip heights as described in Chapter 3). The Hub Height ZTVs, show the number of turbine hubs theoretically visible in the Study Area (hub heights are derived from the turbine rotor and hub height dimensions listed in Chapter 3). When used in conjunction with the Blade Tip ZTV, the Hub Height ZTV provides an indication of the degree to which the wind turbines may be visible.
- 5.11.2 There are limitations in this theoretical production, and these should be considered in the interpretation and use of the ZTVs:
- 5.11.3 the ZTVs illustrate the 'bare ground' situation, and do not take into account the screening effects of vegetation, buildings, or other local features that may prevent or reduce visibility;
 - the ZTVs are based on theoretical visibility from 2m above ground level;

- the 45 km ZTVs are based on a 50 m data grid (Ordnance Survey (OS) Digital Terrain Model (DTM)) and the 20 km ZTVs are based on 5 m data grid (OS Terrain 5), therefore relatively small changes in elevation may not be accounted for;
- the Blade Tip ZTV does not indicate the decrease in visibility that occurs with increased distance from the Proposed Scheme. The nature of what is visible from 3 km away would differ markedly from what is visible from 10 km away, although both are indicated on the Blade Tip ZTV as having the same level of visibility; and
- there is a wide range of variation within the visibility shown on the ZTV, for example, an area shown on the Blade Tip ZTV as having visibility of large numbers of turbines may gain views of the smallest extremity of blade tips, or of many full turbines. This can make a considerable difference in the effects of the Proposed Scheme on that area. The Hub Height ZTV should be used in conjunction with the Blade Tip ZTV to provide an indication of the degree to which the wind turbines are visible.

5.11.4 These limitations mean that while the ZTV is used as a starting point in the assessment, providing an indication of where the Proposed Scheme would theoretically be visible, the information drawn from the ZTV is checked in the field, to ensure that the assessment conclusions represent the visibility of the Proposed Scheme reasonably accurately.

5.11.5 using ArcGIS 10.7.1 Viewshed Tool and the same data as the other ZTVs. The Horizontal Angle ZTV show the horizontal field of view (in degrees) that may be affected by views of the turbines.

Visualisations

5.11.6 The viewpoint assessment is illustrated by a range of visualisations, including photographs and photomontages, which accord with NatureScot's Visual Representation of Wind Farms Version 2.2 (NatureScot, 2017). 'Visualisations of windfarms have a number of limitations when using them to form a judgement on a windfarm proposal. These include:

- a visualisation can never show exactly what the windfarm would look like in reality due to factors such as: different lighting, weather and seasonal conditions which vary through time and the resolution of the image;
- the images provided give a reasonable impression of the scale of the turbines and the distance to the turbines, but can never be 100% accurate;
- a static image cannot convey turbine movement, or flicker or reflection from the sun on the turbine blades as they move;
- the viewpoints illustrated are representative of views in the area, but cannot represent visibility at all locations;
- to form the best impression of the impacts of the windfarm proposal these images are best viewed at the viewpoint location shown; and
- the visualisations must be printed at the correct size to be viewed properly.'
- The photographs used to produce the photomontages have been taken using Canon EOS 5D and 6D Digital SLR cameras, with a fixed lens and a full-frame (35 mm negative size) CMOS sensor. The photographs are taken on a tripod with a pano-head at a height of approximately 1.5 m above ground.

5.11.7 To create the baseline panorama, the frames are individually cylindrically projected and then digitally joined to create a fully cylindrically projected panorama using Adobe Photoshop or PTGui software. This process avoids the wide-angle effect that would result should these frames be arranged in a perspective projection, whereby the image is not

faceted to allow for the cylindrical nature of the full 360-degree Horizontal Field of View (HFOV) but appears essentially as a flat plane.

- 5.11.8 Tonal alterations are made using Adobe software to create an even range of tones across the photographs once joined.
- 5.11.9 The photographs are also joined to create planar projection panoramas using PTGui software. These are used in the creation of the 53.5 degree field of view photomontages. In some views, more than one 53.5 degree field of view panorama is prepared, in order to accommodate the full width of the Proposed Scheme.
- 5.11.10 Wireline representations that illustrate the Proposed Scheme model set within a computer-generated image of the landform are used in the assessment to predict the theoretical appearance of the turbines. These are produced with Resoft Wind farm software and are based on OS terrain 5 terrain model. There are limitations in the accuracy of DTM data so that landform may not be picked up precisely and may result in turbines being more or less visible than is shown, however, the use of OS terrain 5 minimises these limitations. Where descriptions within the assessment identify the numbers of turbines visible this refers to the illustrations generated and therefore the reality may differ to a degree from these impressions.
- 5.11.11 Photomontages have been produced for the majority of views, again using ReSoft WindFarm software, to provide a more realistic image of the appearance of the Proposed Scheme. In most views these include the introduction of the turbines only as these are the elements that create the greatest change in views and are likely to be most visible from the surrounding area. Where there is notable visibility of site infrastructure and where practical, this is shown in the photomontages and is generated using a combination of 3D software such as Topos, Visual Nature Studio, Sketchup and 3D Studio Max.
- 5.11.12 The baseline photographs and cumulative wireline visualisations shown for each viewpoint cover a 90-degree HFOV (or in some cases, up to 360-degree), which accords with NatureScot guidance. These are cylindrically projected images and should be viewed flat at a comfortable arm's length.
- 5.11.13 The 53.5 degree HFOV wirelines and photomontage are prepared using a planar projected image and should also be viewed flat at a comfortable arm's length. These images are each printed on paper 841 x 297 mm (half A1) which provides for a relatively large scale image.
- 5.11.14 The 53.5 degree photomontage view does not always include a view of key existing windfarms in the view and it is important therefore that the 90 degree baseline panoramas provided are reviewed alongside the 53.5 degree photomontages when reviewing the visualisations so that these existing windfarms are properly taken into account.
- 5.11.15 In the wirelines, the turbines are shown with the central turbines facing the viewer directly, with the full rotor diameter visible at its tallest extent. In the photomontages, the turbine rotors are shown with a random appearance with the central turbines facing the viewer directly. In the night-time photomontages, lights are shown as visible and without obstruction from turbine blades.
- 5.11.16 The photographs and other graphic material such as wirelines and photomontages used in this assessment are for illustrative purposes only and, whilst useful tools in the

assessment, are not considered to be completely representative of what would be apparent to the human eye. The assessments are carried out from observations in the field and therefore may include elements that are not visible in the photographs.

- 5.11.17 The night time photography has been captured in low light conditions, when other artificial lighting (such as street lights and lights on buildings) is on, to show how the wind farm lighting would look compared to the existing baseline at night. In terms of how lighting is captured in visualisations, the main change in the latest version of the NatureScot guidance 'Visual Representation of Wind Farms' (Version 2.2, February 2017) is in paragraphs 174-177, which states: *'The visualisation should use photographs taken in low light conditions, preferably when other artificial lighting (such as street lights and lights on buildings) are on, to show how the wind farm lighting will look compared to the existing baseline at night'...* *'We have found that approximately 30 minutes after sunset provides a reasonable balance between visibility of the landform and the apparent brightness of artificial lights, as both should be visible in the image.'* NatureScot also recognises the challenges of capturing night time photography and accept that some post photographic manipulation of images to provide a good representation is acceptable.

5.12 Viewpoint Selection Rationale

- 5.12.1 The final list of viewpoint locations used in the LVIA is provided in the Chapter 5 along with details on the receptor type, distance / angle of view to the Proposed Scheme along with landscape character and designations that the viewpoints are located in.
- 5.12.2 In addition to those viewpoints initially proposed by the applicant, a large number of viewpoint locations were also suggested through consultation feedback from Natural Resources Wales, Merthyr Tydfil County Borough Council and Caerphilly County Borough Council. The selection rationale for these additional suggestions is outlined in Table 5.1.5 below. It should also be noted that some of the viewpoints initially proposed by the applicant have been relocated or removed during this process in favour of other suggested locations, as outlined in Table 5.1.5. Field survey and photography has resulted in more precise locations for viewpoints included in the LVIA and the grid refs for LVIA viewpoints are therefore slightly different than the initially proposed or suggested grid refs.

Table 5.1.6: Viewpoint selection rationale

Viewpoints Considered	Grid Ref		Suggested by	Selection Rationale
Pen Garnbugail	310048	203560	Merthyr Tydfil County Borough Council	Included in LVIA. Represents elevated views from the south and compliments the lower elevated viewpoint location at Fochriw.
Cyfartha Park	304568	207411	Merthyr Tydfil County Borough Council	Included in LVIA. Whilst there is no theoretical visibility within the main areas of the park and garden (west of the playing fields) this viewpoint represents visitors to the eastern part of the parkland.

Viewpoints Considered	Grid Ref		Suggested by	Selection Rationale
Mynydd Aberdar	302106	205568	Merthyr Tydfil County Borough Council	Wireline only. Proposed viewpoint on Meardy Rd is in a similar view direction representing views from the west, albeit at greater distance.
Dowlais	306742	207891	Merthyr Tydfil County Borough Council	Not included. Whilst the ZTV shows theoretical visibility across this area of settlement, the intervening woods and built settlement in views towards the site limits visibility and the potential for visual effects. An additional viewpoint from Trefechan has been included to represent elevated areas of the settlement where less obstructed views towards the Proposed Scheme can be found. Dowlais is also considered in the RVAA.
Trefechan	303607	208881	Merthyr Tydfil County Borough Council	Included in LVIA. Represents elevated areas of the Merthyr Tydfil settlement that have relatively unobstructed views towards the Proposed Scheme.
Pontsticill	305620	211182	Merthyr Tydfil County Borough Council	Included in LVIA. Represents views from the Pontsticill settlement to the west of the Proposed Scheme.
PRoW (Gelligaer FP101)	309828	210056	Caerphilly County Borough Council	Included in LVIA. Represents close range views from nearby PRoW immediately southeast of the site.
Fochriw	310774	206017	Caerphilly County Borough Council	Included in LVIA. Represents views from the edge of settlement and Rhymney Valley Ridgeway Walk.
Rhymney common	311896	208674	Caerphilly County Borough Council	Included in LVIA. Represents elevated views from Rhymney common that overlooks the Rhymney settlement edges in the view towards the site.
Manmoel Road	317010	205650	Caerphilly County Borough Council	Not included. Cefn Manmoel, Sirhowy Valley Walk is in a similar and closer location.
Bute Town Reservoir PRoW	310320	209075	Caerphilly County Borough Council	Relocated. The viewpoint at A469 / Bute Town, which overlooks the reservoir, has been relocated to represent this receptor

Viewpoints Considered	Grid Ref		Suggested by	Selection Rationale
Bute Town Conservation Area & Cycle Route	310391	209337	Caerphilly County Borough Council	Relocated. The viewpoint at A469 / Bute Town, which is at the edges of the conservation area with views towards the site area, has been relocated to represent this receptor
Bridleway Gelligaer BR 103	309130	209093	Caerphilly County Borough Council	Relocated. The viewpoint on the A465 has been relocated to represent this receptor.
PRoW (Bedwellty FP 28)	315970	201612	Caerphilly County Borough Council	Included in LVIA. Represents elevated views along the Rhymney Valley from this elevated PRoW.
Garn Ddu	302758	212400	Natural Resources Wales	Included in LVIA. Represents elevated east facing views towards the site from within the southern edges of Bannau Brycheiniog National Park.
Cefn Cil- Sanws	302450	210269	Natural Resources Wales	Not included. Garn Ddu selected to represent suggested viewpoint at southern edges of BBNP.
Craig Fan Ddu, Cairn	308626	210759	Natural Resources Wales	Wireline only. Wireline included as additional reference to the views from longer walks around the Brecon's horseshoe.
Mynydd Llangynidr	312343	215134	Natural Resources Wales	Wireline only. Viewpoint on the B4560, albeit more distant, represents elevated west facing views towards the site from within the southern edges of BBNP. Viewpoint at Trefil although not within BBNP is located at a similar distance to Mynydd Llangynidr.
Fan Fawr	296462	218942	Natural Resources Wales	Wireline only. Pen y Fan (included in LVIA) represents a worst case view from elevated locations at this distance from within the Bannau Brycheiniog National Park.
Cadair Fawr	297792	212314	Natural Resources Wales	Wireline only. The additional Garn Ddu viewpoint is closer to the site and in a similar view direction.
Gelli-gaer Common	310073	204677	Natural Resources Wales	Not included. It is considered that the viewpoints included at Fochriw and Pen Garbugail are suitably representative of available views from the Gelligaer Common.

Viewpoints Considered	Grid Ref		Suggested by	Selection Rationale
A4233 Meardy Rd	299524	201562	Applicant	Included in LVIA. Represents elevated views from the west, in particular on the top of valley section of the A4233 that looks across Mynydd Aberdar.
A465 / Heads of the Valleys Road	309109	209001	Applicant	Included in LVIA. Represents close proximity views from the busy A465. Relocated to also represent the nearby Bridleway Gelligaer BR 103.
Pant, Merthyr Tydfil (NCN 46)	307030	209140	Applicant	Included in LVIA. Represents close proximity views from the edges of Pant a northern suburb of Merthyr Tydfil.
Cefn yr Ystrad	308788	213618	Applicant	Included in LVIA. Represents recreational receptors on the moorland at the southern edges of the BBNP.
Waun y Gwair	307937	212114	Applicant	Not included. Within a large area of boggy moorland which is difficult to access, therefore, recreational receptors would not often cross this area. The nearby viewpoint at Cefn yr Ystrad is closer to paths with easier access and therefore better represents recreational interests in this area of BBNP.
Pant Station, Brecon Mountain Railway	305951	209655	Applicant	Included in LVIA. Represents visitors to the Brecon Mountain Railway at the edge of the BBNP.
A469 / Bute Town (NCN 468)	310359	209123	Applicant	Included in LVIA. Represents road users on the A469 but has also been relocated to represent Bute Town and the Reservoir PRoW.
Rhymney	311129	209007	Applicant	Included in LVIA. Represents elevated settlement receptors at the northern edges of Rhymney, closest to the Proposed Scheme.
Tynewydd, to the north of Tredegar	312589	211154	Applicant	Relocated. Following field survey, viewpoint relocated to Deighton Playing Fields within Tredegar.
Tredegar, Deighton Playing Fields	314072	209747	Applicant	Included in LVIA. Represents relatively unobstructed views from within the Tredegar settlement.
Trefil	312247	212717	Applicant	Included in LVIA. Represents views from the Trefil settlement.

Viewpoints Considered	Grid Ref		Suggested by	Selection Rationale
Cefn Brithdir, Rhymney Valley Ridgeway Walk	312778	203875	Applicant	Wireline only. This location on the Rhimney Valley Ridgeway Walk is more distant when compared to the additional location suggested by Caerphilly County Borough Council at Fochriw, also on the Ridegway Walk. Viewpoint replaced by the location at Fochriw.
Cefn Manmoel (Sirhowy Valley Walk)	316199	207460	Applicant	Included in LVIA. Represents views from the Sirhowy Valley Walk and elevated ridgeline.
Beacons Way (Craig Y Fan Ddu)	305430	218342	Applicant / NRW	Included in LVIA. Represents walker at the southern edges of the Brecon's 'horseshoe' ridge.
B4560, Cefn Pwll-coch	316452	214476	Applicant	Included in LVIA. Represents views west from an elevated road that crosses the southern edges of the BBNP.
Mynydd Carn-y-cefn	318408	208054	Applicant	Included in LVIA.
A4059	298754	216122	Applicant	Included in LVIA. Represents views south from an elevated road within the BBNP.
Pen y Fan	301229	221547	Applicant	Included in LVIA. Represents views from the most elevated and popular hill top with the BBNP.
Mynydd Cefn-y-Gyngon	296323	203495	Applicant	Wireline only. Replaced with a viewpoint at A4233 Meardy Rd, which is at a similar distance angle of view and captures the larger numbers of receptors within local communities that use this road.
The Black Mountains, Pen Cerrig-calch	321708	222371	Applicant	Included in LVIA. Represents elevated views from the northeast part of the BBNP.
Sugar Loaf	327231	218775	Applicant	Included in LVIA. Represents elevated views from the east part of the BBNP from a popular and easy to reach hilltop.
